they can no longer afford because premiums rise with age. They expect the same service now that they have more need of health care, from the NHS. This may lead to a higher rate of requests for referral to secondary care. It can take a lot of time, patience, and repeated visits to try to educate this group to have more realistic expectations of the service and to keep patients away from unnecessary and expensive secondary care.

In conclusion, we believe that population age, the availability of family support, rurality, and patient expectations may have as much, if not more, of an influence on GP workload as population deprivation. Furthermore, any reduction in GP funding may lead to an inadequate gatekeeper role and increased use of expensive secondary care. We’re all GPs and we’re all in at the deep end paddling hard to keep afloat.

Asymptomatic COPD and NICE guidelines

The continuing discrepancy between national and international guidance is unhelpful for patients, doctors, policy makers, and researchers because the Global initiative for chronic Obstructive Lung Disease (GOLD) does not require the presence of subjective symptoms (cough, sputum production, shortness of breath), whereas NICE guidance states that symptoms are a requirement for diagnosis and classification of chronic obstructive pulmonary disease (COPD).1 Why does the National Institute of Health and Clinical Excellence (NICE) persist with this discrepancy when there is substantial evidence that reported symptoms are unreliable for diagnosis?

For example, among 5000 people from those included in the Third National Health and Nutrition Examination Survey in the US, 70% of those with undiagnosed early airways obstruction, and up to 50% of undiagnosed stage 3 chronic obstructive pulmonary disease denied having cough or phlegm, and 40% denied a wheeze.2 A longitudinal study of over 2000 patients with COPD, from 12 countries, found that ‘among subjects with severe airflow obstruction, a substantial proportion did not report symptoms’. About 40% of those in the GOLD severe category denied being breathless (modified MRC dyspnoea scale 0 [10%] or 1 [30%]).3 Likewise, among a large population survey in China of 20 000 people over 40 years of age, 8% were found to have COPD of whom 35% had no symptoms (they said ‘no’ to the questions: ‘do you have cough, phlegm,
Screening for atrial fibrillation

I was reading with interest the article of Lewis et al about the use of a new gadget for the detection of atrial fibrillation in general practice. The diagnosis of atrial fibrillation is very important, but do we need to invest in further instruments to screen for atrial fibrillation?

I think a cardiac auscultation should be part of a consultation, especially in the high older risk group. I diagnosed people in their 50s with atrial fibrillation who consulted me for their phimosis or for losing weight. Initially amused about the cardiac auscultation they were very thankful when I explained that their heart rhythm, if not treated, could cause serious problems in the future, for example, stroke.

Despite having had several consultations as a patient with several GPs in my life, no one checked my blood pressure or did auscultate my heart as yet (despite me being in my 50s). We have to come back to the physical examination that is more cost-effective and a quick screening tool when it is combined with prior adequate training and clinical reasoning. Not only are rhythm disturbances important, but structural heart disease can be asymptomatic, for example, in aortic regurgitation, despite being a serious cardiac abnormality.

Normal physical examination can exclude valvular regurgitation in asymptomatic patients, and no echocardiogram is necessary. If GP colleagues feel rusty regarding cardiac auscultation there are very good websites available to update oneself with murmurs and rhythms, or one could sit in with a cardiologist colleague. One good heart sound tutorial, that is available free on the internet is ‘Blaufuss Multimedia — Heart Sounds and Cardiac Arrhythmias’. I hope that we are all listening to the patient more. This is not meant only for the soul, but applies to the body as well.

Integrated medicine

Brien et al interviewed 35 patients who were using complementary and alternative medicine (CAM) in parallel with orthodox medicine. They state that ‘there has been no direct research into how individuals use CAM and OM (orthodox medicine) in relation to each other ...’. This may not be entirely correct. In 1997, we published a survey of 3384 arthritis sufferers and analysed the data of 496 patients using both orthodox medicine and CAM. Our results suggested that orthodox medicine was generally perceived as more effective but the therapeutic encounters with providers of CAM were perceived as more satisfying. For instance, 64% of patients felt that CAM clinicians spent enough time with them, while, for orthodox doctors, the figure was only 45%. Brien et al show that, predictably, patients use CAM and orthodox medicine in ‘different ways’. I suggest that our 1997 findings go some way in explaining why.
