The importance of considering sebaceous gland carcinoma in presumed chalazia in South Asian patients?

A 51-year-old Malaysian female was referred with a left lower eyelid lesion noticed 4 years ago. She consulted her GP a year ago and was diagnosed to have a chalazion. Her GP requested funding for treatment. The primary care trust (PCT) considered this a low-priority procedure and declined funding. One year later she approached her GP again and was referred to a hospital for management of this eyelid lesion (Figure 1). She underwent a biopsy and the histology was suspicious of a squamous cell carcinoma. She was referred to our unit. On examination, she had a left lower eyelid, firm 4mm nodule with thickening and distortion of tarsal conjunctiva. With a clinical suspicion of sebaceous gland carcinoma (SGC), a wedge excision of the lesion was performed. Paraffin section histology confirmed complete excision of SGC. Delayed repair required a Tenzel flap. She remains asymptomatic at 5-month follow-up.

Discussion

Eyelid SGC is known to masquerade as chalazion.1 Patients with longer duration of symptoms have been reported to have more advanced disease and higher rates of recurrence or metastasis. Delay in diagnosis and treatment of SGC by more than 6 months has been reported to be associated with increased incidence of recurrence.2 In this case of SGC the treatment was denied by a PCT, after mis-diagnosis as a chalazion, considering it as a low priority procedure.

Although criteria may vary, PCTs only fund excision of chalazion if the chalazion has been present for more than 6 months, it is situated on the upper eyelid, and it is causing blurring of vision.

REFERENCES

Figure 1. Lower eyelid lesion.

SGC is more common in the upper eyelid than lower, with ratios varying from 1.3 to 3. The above PCT criteria could lead to a delay in diagnosis of a SGC masquerading as chalazion in the lower eyelids. SGC is rare in the white population, accounting for 1–5.5% of all eyelid malignancies.3,4 However, SGC appears to be much more common in the Asian population (South Asian and Indian), accounting for 27–40% of all eyelid malignancies.3,4 Hence, the possibility of SGC should be considered in Asian individuals presenting with persistent chalazion. Persistent or recurrent chalazion and increase in size of lesion particularly in individuals of Asian origin should justify early referral to the ophthalmologist.
