**Boring but important: the community mental health team**

Green and Gowans are right to worry about what has happened to the seriously mentally ill when the number of psychiatric beds has been mercilessly cut. However, it may be misleading when they talk of a lack of evidence for community teams and then talk about crisis teams (CTs). The fact that CTs — often heralded as ‘the’ alternative to admission — perform poorly under scrutiny does not mean that community care is by necessity poor.

The rise of the so-called functional teams — CT, assertive outreach (AO), early intervention for psychosis — has not led to great (or at least greatly demonstrable) advantages for patients. A particularly salutary tale comes from the work of Killaspy et al. They used the community mental health team (CMHT) as treatment-as-usual comparator for an intensive case management model, the AO team. But be careful what the placebo is. While brief follow-up looked promising, this longer follow-up eventually found AO to do scarcely better than the CMHT for a lot more clinical effort and presumably, cost.

Early intervention for psychosis services, too, have had questionable benefits. Early intervention for psychosis — has not led to great (or at least greatly demonstrable) advantages for patients. A particularly salutary tale comes from the work of Killaspy et al.

The CMHT suffers from having come into the world essentially before the era of the randomised controlled trial, but some other research also indicates its usefulness among even the most severely ill long-stay patients.

The authors here hint at a problem at the other side of the hospitals, acute presentation, which may explain their focus on CTs. When justly lamenting the increasingly poor provision of inpatient care for the most mentally ill in our society, though, it is as well to talk of the tangible relative success of the CMHT rather than the straw man of the CT.

**Invest in community-based solutions that address individuals’ needs: not more beds**

While I agree with Green and Gowans that reductions in psychiatric bed availability have driven the reduction in admissions, there has been considerable investment in home treatment/crisis teams to support the policy. In contrast to many policies directing reorganisation of services there is relatively good evidence that home treatment teams can support individuals to stay safely out of hospital and provide a better experience of care during a crisis. While practice is highly variable, and this needs addressing, I have witnessed first-hand the benefits of a well-functioning crisis team and inpatient acute care system. Analyses of admission decisions also suggest that many inpatient stays are not necessary. The problem is likely to lie in implementation and a risk aversive culture in the NHS.

While we need to optimise our response to crises, it is possibly more important to focus on generating positive outcomes; there are a range of community-based interventions, such as early intervention for psychosis, smoking cessation, and support into work which are likely to be cost-effective. Community-based mental health services need to be able to perform three interlinked key functions, and general practice has a role to play in each:

- promoting better mental health and social outcomes, such as feelings of resilience, hope and wellbeing; having a home, and being in work;
- proactively managing specific short and longer term mental health problems, such as bouts of depression with anxiety, relapsing post-traumatic stress disorder with comorbid substance use, and the physical health needs of individuals with psychosis and dementia; and
- anticipating and responding to crises.

I suggest that future research should not be centred primarily around the epidemiology of the current inherently flawed diagnostic classification system, as implied by Green and Gowans, but should instead focus on understanding individuals’ needs for services (along with their strengths and resources). Patients’ personal goals, the links between their individual patterns of emotion, thinking, behaviour, and social situation define the services that are needed. Alongside self-management, carers, and family, resources

Digital mental health services in general practice

Claire Harding and colleagues have highlighted the potential of digital interventions in general practice and the need for NHS accredited or ‘kitemarked’ apps, but also raise questions about the need for evidence of their safety and efficacy.

They state that ‘... there is broad consensus in the field that traditional randomised controlled trials are not fit for purpose with digital interventions [largely because services develop and expectations change faster than trials can be run] ...’. We acknowledge that good interventions take time to develop and test, but do not agree that this is a reason to abandon evidence-based practice. Users and commissioners should expect robust evidence before choosing to invest time or resources in such interventions.

For simple health information on the web, common sense ‘kitemarking’ may be sufficient. However, for interventions aimed at behaviour change, randomised controlled trials are warranted, regardless of whether they are delivered digitally. Rapid changes in services are not sufficient reason to negate this necessity, as well-developed interventions can be adapted to new delivery systems.

Endometriosis in secondary care

As a hospital gynaecologist I may not be the best person to comment on your article but these are my thoughts. Symptoms that could be due to endometriosis are extremely common in both primary care and the hospital gynaecology clinic. With the exception of women who are currently trying to conceive, it is perfectly reasonable to treat these symptoms hormonally. The earlier Royal College of Obstetricians and Gynaecologists guideline as well as the more recent European guideline quote, both recommend treating symptoms with either the combined contraceptive pill, an ovulation suppressing progesterone-only pill, or the Mirena® interuterine system. Women referred to hospital because of the supposed importance of early diagnosis may be disappointed to be offered precisely those treatments if they attend a consultant clinic.
