Appraisal, wellbeing, and pandemics: why a focus on wellbeing is always warranted

Doctors are human beings, with personal and professional needs.¹ Many have spent the pandemic supporting others with little support for themselves. The restart of appraisals offers protected time to have a confidential reflective conversation with a well-trained peer. The rebalanced ‘Appraisal 2020’ process² minimises the pre-appraisal paperwork and recognises the impact of the pandemic. We urge doctors to seize this opportunity to make their appraisals valuable and ensure that their investment of time delivers maximum benefit to themselves and their patients.

A focus on wellbeing in appraisal is always warranted. In the World Medical Association Declaration of Geneva, doctors pledge: ‘I WILL ATTEND TO my own health, wellbeing, and abilities in order to provide care of the highest standard.’ A doctor who is unwell cannot give their best care to patients — yet many doctors do not prioritise maintaining their own health and wellbeing. The risk of burnout for doctors was high even before the pandemic. Appraisal, as a process reaching all, is a proactive way to offer a safe place to discuss any concerns and be signposted to resources as needed.

Doctors should understand the code of conduct that defines the limits of professional confidentiality in any setting. If a doctor discloses a risk to personal or patient safety, appropriate action must be taken immediately to protect the vulnerable. An appraisal would be stopped — but so would a casual coffee-room conversation. Sensitive topics are frequently discussed at appraisal without being recorded. The written summary should always be sent in a confidential reflexive conversation. The risk of burnout for doctors was high even before the pandemic. Appraisal, as a process reaching all, is a proactive way to offer a safe place to discuss any concerns and be signposted to resources as needed.

Appraisal and revalidation — time for a critical look?

The authors do an excellent job of making us think.¹ I agree that the annual appraisal session is totally inappropriate for enquiry into general wellbeing etc. Given that NHS general practice spends a lot of money and time on a process that has never, to my knowledge, been subjected to critical review, might this be a good time to look closely at the effectiveness of appraisal and revalidation?

When is it safe to return to exercise post-COVID-19?

A’Court et al suggest that patients with ‘mild’ COVID-19 illness, and who are asymptomatic, do not need to restrict exercise.¹ While this seems to be a straightforward distinction, new evidence on ‘Long COVID’ presentations even in patients with ‘mild’ illness is starting to raise questions on how we define the severity of COVID illness. The National Institute

When is it safe to return to exercise post-COVID-19?

A’Court et al suggest that patients with ‘mild’ COVID-19 illness, and who are asymptomatic, do not need to restrict exercise.¹ While this seems to be a straightforward distinction, new evidence on ‘Long COVID’ presentations even in patients with ‘mild’ illness is starting to raise questions on how we define the severity of COVID illness. The National Institute
for Health Research recently suggested that patients with ‘Long COVID’ may well represent four subgroups of clinical syndromes, and therefore have different rehabilitation needs.\(^2\)

Often patients report symptoms that are refractory, intermittent, or resolve before returning in episodic bouts (these include muscle aches, chest pains, dyspnoea, and fatigue), many of which are relative contraindications to exercise.\(^3\) The reality of COVID is that the clinical course of infection and recovery does not fit clearly defined categories (of mild, moderate, or severe illness) and symptoms rarely fit into the binary category of cardiac or non-cardiac. In addition to this, patients’ rehabilitation goals are very individual and often relate to their pre-morbid status, and this requires a tailored approach that takes into account the physical demands of their day-to-day activities and occupation.

Ophthalmia neonatorum and the role of primary care

We thank Maqsood and Mahmood for their article on herpes simplex keratitis in neonates,\(^1\) which includes pointers on distinguishing HSV keratitis from other infective causes. While this is an interesting clinical point, we feel that it lacks a primary care perspective. ’Sticky eye’ is a common presentation in newborns, and is usually due to immature nasolacrimal duct formation, which requires no treatment unless it fails to improve by 1 year of age. Ophthalmia neonatorum, whether bacterial or viral, requires urgent secondary care input for full assessment and treatment.\(^2\) As discussed in the article by Maqsood and Mahmood, eye infections in the newborn are unlikely to present with features that clearly distinguish benign infections from more significant causes. While the frequency with which HSV causes eye infections in newborns is not stated, we presume that it is uncommon enough that many GPs will not see a case during their career. It is difficult to have a high index of suspicion for such a specific yet infrequently occurring event. We therefore suggest that primary care practitioners need only to distinguish infective from non-infective causes of ocular discharge in neonates, and urgently refer all neonates with suspected infection, while avoiding unnecessary treatment for a newborn with a blocked tear duct.

A good death is much more than anticipatory drugs

It is interesting to read Bowers et al’s article\(^3\) as it confirms general practice response in the UK is quite variable as regards end-of-life care. Over a decade ago, the Department of Health published its white paper on End of Life Care Strategy\(^2\) in it, four elements were considered (dignity in treatment, adequate symptom control, familiar surroundings, and people). To achieve a ‘good death’, having the right conversation is paramount; equally is having adequate coordination among the different professionals looking after the patient, the origin of the Electronic Palliative Care Coordination Systems (EPaCCS) currently in use in different shapes and forms across the UK.\(^3\) The ability to have early anticipatory drugs as part of advanced care plans shared among organisations (district nursing, out of hours, GPs) is a core element.\(^4,5\)

The question is whether anticipatory drugs are the initial step, as it seems implied in the article, or whether it is the careful discussion with patients and families of the end of the road and the planning of all aspects of care, of sharing information, of required coordination, of support available. The use of anticipatory drugs should not be discussed in isolation. Understanding the patient’s preferences for end-of-life care, including preferred options for the place of care as well as the place of death, and any other personal views, must take place. A coordinated and holistic approach is the only way to achieve a good death.
