Abstract

Background: Primary care and community healthcare professionals (HCP) are well placed to discuss child excess weight with parents and support them to make changes. However, HCPs have concerns about doing this. There is a need to understand the factors that influence HCPs in undertaking these activities to inform strategies to support them.

Aim: To explore with HCPs working in primary care and community settings their experiences of having conversations about child weight with parents, and the factors that create barriers or facilitate them to have these conversations.

Design and setting: A qualitative study with General Practitioners (GP), Primary Care Nurses (PN), and School Nurses (SN) in England.

Method: GPs and PNs were recruited to participate in semi-structured interviews. SNs from a community healthcare NHS trust were recruited to participate in focus groups. Vignettes were used to stimulate discussion. Data were analysed guided by the Framework approach.

Results: 13 GPs, 7 PNs, and 20 SNs participated. Identified barriers included structural, HCP-related and parent/family-related factors. Facilitating factors for having conversations with parents about child excess weight included structural changes (e.g. dedicated appointments, access to weight assessment data, joined up working across agencies), specific approaches adopted by HCPs, and enhancing HCPs’ skills (general and weight management-related) and knowledge of child weight management services.

Conclusion: A range of barriers exist to HCPs addressing child excess weight with parents in primary care and community settings. Actions to effect structural changes and support HCPs in developing relevant knowledge and skills are required to overcome these.

Keywords: Primary Health Care; General Practice; School Nursing; Child; Paediatric Obesity; Qualitative Research.
**How this fits in:** Healthcare professionals (HCPs) working in primary care and community settings are known to experience barriers in discussing child excess weight with parents. We conducted a qualitative study with General Practitioners, Primary Care Nurses and School Nurses to further explore these barriers and identify facilitating factors to inform recommendations for actions to support HCPs in addressing child weight with parents. Structural changes within primary/community care, joined up systems and data sharing across agencies, and development of HCP knowledge and skills through core training and continuing professional development will enable HCPs to discuss child weight and provide advice to parents.
**Introduction**

There has been increasing focus on the role of General Practitioners (GPs) and other primary care and community healthcare professionals (HCPs) in health promotion, including addressing childhood obesity. However, there is evidence that GPs have concerns about initiating conversations with parents about their child’s weight. Two systematic reviews of qualitative studies conducted with HCPs in high-income countries reported barriers to HCPs having these conversations, including lack of knowledge/competence, time and clear referral pathways, concern about the HCP-patient relationship, social and cultural factors, and limited ability to address child weight without the support of other agencies. There has been less research to more directly inform the strategies and support required to facilitate HCPs in having conversations about child weight with parents. In a 2018 meta-synthesis of 13 studies, some factors that HCPs found helpful when discussing child weight were identified. These mainly related to approaches to interacting with families and tools to assess child weight.

In England, there is a programme of routine assessment of child weight: the National Child Measurement Programme (NCMP), which has over 90% coverage and provides BMI data on children aged 4-5 and 10-11 years. Currently this data cannot be routinely accessed in primary care, but there is an aspiration to provide this access in the future (communication from Public Health England) as part of the NHS Digital Child Health Programme, which could assist in supporting HCPs to have conversations about child weight.

In this study we explored GPs’, PNs’ and SNs’ experiences of consultations with parents to address overweight/obesity in children of primary school age (4-11 years). We aimed to gain a deeper understanding of barriers and facilitators to having these conversations to inform potential future strategies to provide support to HCPs. We also explored the role of routinely collected data to support this HCP activity.
Methods

Study design

We conducted a qualitative study with HCPs from November 2019-March 2020. We invited GPs and PNs to participate in interviews, and SNs to participate in focus groups (FGs).

Participants and recruitment

We purposively sampled participants working with populations with high ethnic diversity and socioeconomic deprivation. We advertised to GPs and PNs through primary care networks and social media. We provided monetary compensation for their time.

We invited SNs to participate through the School Health Advisory Service in Birmingham (a large, superdiverse city in England with high deprivation). SNs received a continuing professional development certificate for their participation. Participants provided written consent and completed a questionnaire to provide demographic and professional details. For GPs and PNs, practice postcodes were mapped to the Index of Multiple Deprivation (IMD) deciles.

Data collection

FM conducted interviews with GPs and PNs, either face-to-face or by telephone, enabling in-depth exploration of participants’ experiences. FM and MP conducted FGs with SN teams at their work base, enabling group interaction and sharing of experiences among team members. FM and MP are both positioned within a healthcare/public health perspective.

We developed interview and FG discussion guides by drawing on the published literature, clinical experience of the research team and advice from the Study Steering Group (comprising GP, PN, SN, paediatrician and public health representatives), and additionally addressed issues specified by the public health organisation who funded the study (Public Health England). We incorporated two approaches: 1) narratives from HCPs on their experiences; supplemented with 2) clinical vignettes.
developed in consultation with a HCP advisory group (Table 1 and Supplementary Information S1-S4) to encourage deeper reflection on how participants would approach this sensitive issue. For each participant group, 3 vignettes were developed. Vignettes were discussed in the same way for all participants. Further information on vignette development and use is provided in Supplementary Information S4.

Interviews and focus groups were audio-recorded and transcribed. Throughout data collection, transcripts were reviewed (FM and MP) and sufficient information power\textsuperscript{15} was judged to be reached after 20 interviews and three FGs. FM kept a research journal during data collection which informed analysis.

**Data analysis**

Analysis was conducted using QSR NVivo 12 software\textsuperscript{16} and guided by the framework method.\textsuperscript{17} An initial high-level framework was defined. Transcripts were coded using inductive thematic analysis\textsuperscript{18} and situated within the high-level framework. Two transcripts were coded independently by FM and MP and discussed to develop initial codes. Other transcripts were coded by FM. The data were charted to develop a framework matrix, which enabled identification of themes and subthemes. These were reviewed by the research team.

**Results**

Thirteen GPs and 7 PNs from 7 different Local Authority areas in the West and East Midlands regions of England participated in interviews (average duration 50 minutes). Twenty SNs participated in three FGs (average duration 62 minutes). Participant characteristics are presented in Table 2.

We identified three themes related to barriers to HCPs having conversations with parents about child weight, which were: structural and organisational; healthcare professional-related; and family-related.

We identified a further three themes related to facilitators to having these conversations, which were: structural changes; the approaches HCPs take to having these conversations; and the skills of HCPs and their knowledge of relevant structures and services. The themes and related subthemes are presented
in Figure 1 and additional quotes corresponding to each subtheme are presented in Supplementary Information S5.

**Barriers to HCP conversations with parents about child weight**

*Theme: structural and organisational*

Limited time and capacity were commonly cited as barriers, with HCPs identifying that dealing with the primary presenting issue left them with little time for opportunistic intervention. Although all participating HCPs felt well placed to address child overweight with parents, some felt that proactive child weight management intervention was beyond the remit of their role. SNs expressed that health promotion, such as addressing child overweight, was no longer in their role description and they were expected to focus on other priorities. Some GPs felt that addressing child weight was a marginal part of their role.

“Time, because usually they come in about something else. So, if you have got the worries about weight, often, we basically don’t have time.” (GP 06)

“We’re not commissioned to do that anymore. But then most of us feel that’s where our work lies.” (SN; FG01)

Although the HCPs recognised they had a role in providing child weight management advice, they felt limited in what they could offer, and the lack of referral opportunities deterred them from initiating conversations with parents.

“Unfortunately we haven’t got access to a specific dietitian for children for obesity. If you refer them it tends to be rejected” (PN 06)

When asked about access to existing information on child weight status, GPs and PNs discussed that they had no access to this data from other sources (e.g. the NCMP) and that if they had ready access to this and tools to assist in overweight/obesity assessment, they could more easily address the issue with
families. Many participants discussed the need to integrate data from different sources so weight could be longitudinally tracked in primary care, but acknowledged there was no current capability for this.

“I think it [NCMP data] would be helpful…you’re [then] not just solely relying upon your visual recognition of whether the child is a little overweight or not, but actually you’ve got something there, and that would actually help the conversation with parents” (GP 01)

Some GPs and PNs discussed time and cost barriers to attend the training needed to help them have these conversations with parents (see HCP-related barriers).

“…most training is in the core working hours. But if you’re away then you have to put somebody [in your place]. Then it's going to cost an arm and a leg to do that.” (GP 04)

Theme: HCP-related

Some GPs and PNs feared that raising the issue of child weight would damage their relationship with the parent, especially when parents were attending a consultation with a differing agenda. They felt that parents who were unprepared for a conversation about child weight could be defensive. Some HCPs did not feel confident in raising the issue, and this was sometimes related to the HCP living with overweight themselves. Another factor related to HCP confidence was their perceived low awareness of different cultures, both in terms of understanding of how childhood overweight may be viewed and providing culturally appropriate advice.

“If they [the parents] are quite standoffish already as it is... it’s quite hard to then start bringing up their child’s weight” (GP 05)

“…you can sometimes feel that the family might be a bit ...they’re coming for a different thing and this was not on their agenda today. It was not on their radar” (GP 09)

“That’s [cultural beliefs relating to child weight] one of the things I’m struggling with and I’ll be brutally honest... It’s those cultural beliefs I’ve not got a handle on yet.” (GP 03)
The use of BMI centiles by HCPs to assess overweight was identified as an issue. SNs had a good understanding of BMI centile charts, but some expressed mistrust in them, preferring to use height and weight centile charts to assess overweight. GPs and PNs were less familiar with BMI centiles, with some also perceiving that BMI is not a good measure for younger children.

“we used to use the [height and weight] centile charts and actually the BMI will put a lot more children in an overweight category than the centile charts will.” (SN; FG01)

When asked about the skills and training needed, participants often highlighted the limited training that the HCPs receive on childhood obesity and nutrition, which contributed to reluctance to initiate conversations about child weight.

“And I think it’s a problem that lots of people would like to tackle but they just don’t really know where to start...we don’t have much in the way of training about childhood nutrition”

(GP 07)

Theme: family-related

HCPs identified that parents often do not perceive their children (or themselves) to have excess weight, which could be a barrier. In some cases, HCPs discussed this in the context of ethnic and cultural factors.

“I think, in this population the issue is that the certain minorities that we have here, what an ideal or a healthy weight is, isn’t a true reflection of what medically we think is a good weight.” (GP 02)

During discussion of the vignettes, several HCPs acknowledged that challenging family circumstances (e.g. low-income, mental health challenges and parental separation) may make them more reluctant to address child overweight.

“I think it’s quite difficult to talk about weight when they’ve [the family] got so much going on.” (SN; FG01; discussing vignette 3)
SNs particularly saw the feedback letter that parents of children with overweight/obesity receive following NCMP measurement as an issue. The SNs had a role in responding to queries raised by parents following receipt of the feedback letter and discussed that the wording was problematic, often causing anger and distress.

“I’ve have quite a few parents who were very upset receiving the [NCMP feedback] letter. I think it’s more the way the letter is worded.” (FG03; School Nurse)

**Facilitators of HCP conversations with parents about child weight**

**Theme: structural changes**

One strategy identified to address lack of time was making dedicated appointments to discuss child excess weight. There was a sense that this also gave parents time to prepare for the conversation.

“It [discussion about child weight] requires more than the extra 30 seconds I have at the end of the 10 minute consultation. Sometimes I will get over that by saying, “I think we need to discuss your child’s general health, please book a separate appointment to do that.”” (GP 02)

There was a perceived need for more cross-agency working. This related to the integration of data systems to enable HCPs to access and share health information and measurements for children with other healthcare organisations, and to joined up working with schools and other agencies. When asked about which information would be useful to them, HCPs identified that access to and integration of routinely collected data from health services and the NCMP would enable them to easily track children’s weight status and be alerted to children who were rapidly gaining weight.

“...it’s all this collaborative working isn’t it? It’ll stop doing the work twice... and also it’s about being on the same page as well because a parent may come to us and say, “I don’t know what the problem is,” and we can say, “Well actually, let’s have a look at what the school nurse measured”” (PN 03)
Through discussion of the vignettes, access to interpreters for parents with limited English was identified as a facilitator to having conversations about child excess weight in these families. When asked directly about incentives, some but not all GPs identified that incentives through the Quality Outcomes Framework (remuneration to general practices for specified healthcare activities) to proactively address childhood excess weight could be a useful approach. However, some HCPs felt that this may result in a ‘tick box’ approach.

“If the patient spoke limited English but was able to understand some of what I’m saying, I would probably address the main symptom… and then invite them to return with an interpreter for the follow-up appointment.” (GP 10; discussing vignette 1)

“…if you want it done [GPs to have conversations with parents about child excess weight], you have to attach some kind of incentive for all GPs to take it seriously, unfortunately. But at the same time I think there runs the risk of it becoming a tick box exercise, to get that payment” (GP 02)

**Theme: HCP approaches**

HCPs identified several useful approaches to conversations with parents about child excess weight. They described linking weight to the problem that the child was presenting with and giving common sense advice relating to food provision, diet and physical activity. When training and skills were discussed, some highlighted that more training on giving this advice would further facilitate them having these conversations (see HCP knowledge and skills). Many HCPs recognised the need to involve the whole family when providing this advice.

“I would relate it to the problem that they presented with so, “One of the other things that might be a factor here might be that the child is carrying more weight than they should be. And that’s something that you might want to tackle.”” (GP 07)
“I had one mum and her child was overweight, but she was a young parent and she actually didn’t know how to cook the dinners and, yeah... we spent a lot of time with her giving her worksheets, how to cook, make potato and beans rather than going to the fish and chip shop.” (SN; FG03)

Participants discussed signposting or providing lifestyle and weight management resources to families, often highlighting free online materials, such as Change4Life (a national campaign to improve family dietary intake and physical activity). Some participants felt that a more bespoke resource pack containing specific weight management advice for families would assist them in opportunistically addressing child excess weight.

“I think an information package to be able to give to a parent would be great... I think from a healthcare professional point of view, is to give them something to put in their hands, that they will sit and look at when they’ve got five minutes.” (PN 07)

Theme: HCP knowledge and skills

The need for increased HCP knowledge of child weight management services and the requirement to develop certain skills were identified as facilitators. Some HCPs in primary care perceived that there were existing services in their local areas that they could refer to, but it was not always known what these were.

“...offering people services that are available to them, if you know what the services are that are out there, then it makes the conversation a lot easier.” (GP 01)

When asked about skills and training, participants identified generic HCP skills that were helpful to them in having conversations with parents about their child’s weight, including communication skills and being trained to have difficult conversations. Participants also identified useful specific skills, which included skills related to helping patients change behaviour (motivational interviewing), and to providing child weight management and healthy eating advice. Many participants felt that more training on providing this advice would help them address child weight. Some also commented on the
need to consider different cultural contexts when providing healthy eating and weight management advice.

“I think - what’s the term? - motivational interviewing. I’ve done a lot of that in the past. I think that’s useful, looking at motivation to change” (PN 02)

“I’ve never really had any formal training on dealing with obesity in children… I think more practical training [is needed] on what you can actually offer and what is proven to work most effectively.” (GP 02)

Several PNs and SNs discussed the value of learning skills and approaches to having conversations and providing weight management advice from peers.

“What I actually believe as well is sharing the experiences as well; like, you say, “I did this with that one.”” (SN; FG02)

Discussion

Summary

GPs, PNs and SNs recognised the importance of having conversations with parents about child excess weight but they experienced several barriers. Whilst some related to family factors, many were structural or related to the HCPs themselves. We were able to identify facilitating factors for HCPs in having these conversations, which have informed the potential strategies we propose (see implications for practice) that would address both HCP-related and structural barriers within primary and community care. Our study provides valuable new insights on facilitating factors for HCPs, particularly around structural aspects of healthcare and supporting the development of HCPs’ knowledge and skills, as previous research has focused on facilitators relating to HCP-parent interactions.4

Structural changes that would support HCPs in having conversations with parents about child weight relate to organisational aspects within primary and community care (e.g. system of dedicated appointments, better access to interpreters, and financial incentivisation). However, the need for a
more joined-up approach across healthcare organisations and schools, with cross-agency working and sharing of information and weight assessment data (including from the NCMP) was highlighted.

Several approaches that HCPs were already using were identified as good strategies when having conversations with parents about child weight, but participants clearly articulated where they needed further development in their knowledge and skills. This included knowledge of local child weight management provision, and skills in weight management advice and supporting behaviour change. Awareness of the cultural context and the ability to provide culturally appropriate advice were seen as important.

**Strengths and limitations**

This study addressed a knowledge gap relating to strategies to support HCPs in having conversations with parents about child weight. We included the main primary/community care HCP groups that are well placed to address weight in primary school-aged children. We recruited participants serving socioeconomically disadvantaged and ethnically diverse populations, which enabled us to explore the challenges faced within these communities. Our data collection approach included the use of vignettes, which is identified as a valuable method to explore in more depth the challenges faced by HCPs.\(^4\)\(^,\)\(^5\) This was further strengthened by the involvement of a multidisciplinary HCP group, who advised on the development of the discussion guides and vignettes.

Limitations include our focus on the English healthcare context. It is not clear whether these findings would be transferrable to the wider UK and international context, however given the resonance of our findings with the international literature on the barriers to HCPs having these conversations,\(^4\)\(^,\)\(^5\) it is likely that there would be some applicability of our findings to other contexts. Our recruitment approach for primary care professionals depended on advertising so we are likely to have recruited participants with an interest in childhood overweight. Whilst we may have missed differing perspectives from other HCPs, the interest of participants in this topic area helped in terms of exploring potential strategies to facilitate HCPs to address child weight. Our SN participants were from one healthcare organisation, and so SN experiences may have been influenced by the local organisational context,
limiting generalisability. However, this recruitment method allowed us to use FG methodology, which enabled development of participants’ views through discussion with peers. We developed our discussion guides to ensure specific areas that were requested by the funders were covered, which may have influenced the data collected, however we have highlighted in the results where data were obtained in response to specific questions.

**Comparison with existing literature**

Many of the barriers to HCPs having conversations with parents about child weight that we identified have been reported in other studies with HCPs, some of which have been in communities with high deprivation. In line with our findings, barriers identified in these latter studies included under-confidence in initiating discussions, inadequate time, fear of undermining parental trust, lack of recognition of overweight and cultural perceptions of weight by parents, difficulties in and avoidance of giving nutrition advice, and lack of collaborative working with other organisations.

HCPs’ fear of damaging parental trust/relationships, whilst common, may be unfounded. Adults with obesity mostly welcome health professionals initiating conversations about weight, and parents of young children are generally receptive to HCPs discussing child weight. However, the insights of this study’s participants into barriers such as limited cultural awareness and a lack of training and skills in giving weight management advice, reinforce previously identified HCP training gaps. The need to better address cultural competence/safety in GP and nurse training has been highlighted, as has the need for better skills development of medical and nursing professionals in nutrition, and obesity assessment and management. The development of skills and resources to support HCPs in child weight management activities was a prominent facilitating theme in our study. In line with this, a study with English primary care nurses identified training and support in obesity management to be a factor in legitimising their role in undertaking weight management activities. Another factor highlighted was the importance of clarity around the role of the HCP in providing weight management advice, which again resonates with the findings of our study. Qualitative studies with parents of children with excess
weight have also shown that parents want practical and well-informed advice and resources from HCPs to help them manage their child’s weight.\textsuperscript{24, 32}

Our study highlighted the need for awareness of children’s weight management services and joined-up approaches across agencies, including data sharing. A UK-based study exploring adult weight management services and their relationship with primary care identified that there is a need for services to develop better communication and relationships with primary care professionals.\textsuperscript{33} Our findings of the lack of HCPs’ knowledge of children’s weight management services would suggest that there is even greater need to improve communication between primary care and these services. In England, few children have BMI recorded in their primary care health record\textsuperscript{34} and there is evidence that HCPs are not good at identifying children with excess weight using observation alone.\textsuperscript{35} The NCMP provides objective data with high national coverage,\textsuperscript{7, 36} therefore the integration of these data into primary care records represents a key opportunity in supporting HCPs to address child weight with parents. Our findings also suggest that in addition to NCMP data, sharing of information between primary care and other health services would enable more comprehensive engagement with management of child weight.

\textit{Implications for practice}

We have identified several recommendations for actions to address the identified barriers and informed by the identified facilitators to support primary care and community HCPs to initiate conversations with parents and provide weight management advice and support to families. Figure 1 presents these recommendations and outlines which subthemes have informed each recommendation. Clarity around the responsibilities of HCPs is needed. To achieve this, responsibilities need to be defined within primary and community care commissioning arrangements, with adequate time and resource allocated to enable these responsibilities to be fulfilled. To assist in identification and tracking of child excess weight, the sharing of weight assessment data from both the NCMP and other health services with primary care is required. Access to NCMP data in primary care may also enable a more supportive feedback process of NCMP data to parents. Ready access to weight management resources that could
be given to families would support HCPs in the initial management of child excess weight and it would
be important to address cultural diversity in the development of new resources. In addition, there
needs to be a more systematic approach to enabling HCPs to signpost and refer to existing weight
management services through better communication processes between these services and
primary/community care. Finally, the identified training gaps need to be addressed. This should be
done through enhancing core HCP training by the inclusion of generic skills training such as cultural
awareness and competency, as well as more specific training relating to nutrition, and childhood
overweight assessment and management. Additional training could be provided as part of continuing
professional development programmes and incorporate peer/cross-disciplinary learning.

In conclusion, there are actions that could be taken to address the structural and HCP-related barriers
to addressing child excess weight in primary and community care. These will require both national and
local action to implement successfully.

**Funding:** This project was funded by Public Health England. KJ is part-funded by the National Institute
for Health and Care Research (NIHR) Applied Research Collaboration West Midlands. The views
expressed in this article are those of the authors and not necessarily those of the authors’ employing
universities, Public Health England, the National Health Service (NHS), the National Institute for Health
Research (NIHR) or the Department of Health and Social Care.

Figure 1: Barriers and facilitators to healthcare professionals (HCPs) having conversations with parents about child weight: themes and sub-themes, and proposed recommendations for action
### Barriers

<table>
<thead>
<tr>
<th>Structural/organisational</th>
<th>HCP-related</th>
<th>Parent/family-related</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lack of HCP time/capacity</td>
<td>Limited training in weight management/dietary and physical activity advice</td>
<td>Parental perceptions of overweight</td>
</tr>
<tr>
<td>No ready access routinely collected data and other tools to aid child weight assessment</td>
<td>Limited awareness of different cultures</td>
<td>Challenging social circumstances</td>
</tr>
<tr>
<td>Limited referral pathways/services</td>
<td>Lack of confidence in having these conversations</td>
<td>Parental anger at feedback on their child’s weight through the routine National Child Measurement Programme (NCMP)</td>
</tr>
<tr>
<td>Beyond remit of role</td>
<td>Fear of damaging parent-professional relationship</td>
<td></td>
</tr>
<tr>
<td>Limitation of training</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Facilitators

<table>
<thead>
<tr>
<th>Structural changes</th>
<th>HCP approaches</th>
<th>HCP knowledge/skills</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dedicated appointments to discuss child weight</td>
<td>Linking child weight to presenting health issue and discussing health consequences with parents</td>
<td>Increased HCP knowledge of referral pathways/services</td>
</tr>
<tr>
<td>Increased access to interpreters</td>
<td>Providing appropriate dietary and physical activity advice</td>
<td>Communication skills</td>
</tr>
<tr>
<td>Access to data to identify and track child weight status</td>
<td>Involving the whole family</td>
<td>Learning child weight management approaches from peers</td>
</tr>
<tr>
<td>Incentivising through existing primary care structures (e.g. Quality Outcomes Framework)</td>
<td>Signposting to or providing dietary/physical activity resources</td>
<td></td>
</tr>
<tr>
<td>Joined-up systems &amp; cross-agency working</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Recommendations

- **Clearly define responsibilities of HCPs** – ensure child weight management responsibilities are defined in commissioning structures and dedicated time and resource is allocated
- **Increased access to child weight data in primary care** – access to NCMP data and data from other healthcare services; link feedback of NCMP data to parents with further support
- **Support HCPs in providing dietary/physical activity advice** – increase awareness of existing resources; develop resource packs which consider cultural diversity
- **Support signposting and referral to services** – develop processes to ensure HCPs are aware of local children’s weight management services and care pathways
- **Enhance core HCP training** – embed skills/knowledge training into core HCP programmes, e.g. childhood obesity assessment and management, cultural awareness, nutrition
- **Develop continuing professional development (CPD) opportunities** – through professional bodies develop CPD opportunities that encourage cross-disciplinary peer-learning

---

*General Practitioners and Primary Care Nurses only*

The boxes presenting each of the subthemes relating to barriers and facilitators are colour-coded to correspond to the recommendations that they have informed.
